

Smart Technology, Artificial Intelligence, Robotics, and Algorithms (STARA): Employees' perceptions of our future workplace

DAVID BROUGHAM* AND JARROD HAAR**

Abstract

Futurists predict that a third of jobs that exist today could be taken by Smart Technology, Artificial Intelligence, Robotics, and Algorithms (STARA) by 2025. However, very little is known about how employees perceive these technological advancements in regards to their own jobs and careers, and how they are preparing for these potential changes. A new measure (STARA awareness) was created for this study that captures the extent to which employees feel their job could be replaced by these types of technology. Due to career progression and technology knowledge associated with age, we also tested age as a moderator of STARA. Using a mixed-methods approach on 120 employees, we tested STARA awareness on a range of job and well-being outcomes. Greater STARA awareness was negatively related to organisational commitment and career satisfaction, and positively related to turnover intentions, cynicism, and depression.

INTRODUCTION

Top scientists and business people such as Stephen Hawking and Bill Gates have warned of mass unemployment due to the rise of Smart Technology, Artificial Intelligence, Robotics, and Algorithms, which we term STARA (Bort, 2014; Lynch, 2015). It is estimated that one-third of jobs that exist today could be taken by STARA by 2025 (Frey & Osborne, 2013; Thibodeau, 2014). This is due to significant improvements in robotic dexterity and intelligence, coupled with inexpensive autonomous units that have the potential to outperform humans at many manual and conceptual tasks (Frey & Osborne, 2013).

Examples of these types of technology can be seen with the popularisation of retail self-checkouts, smartphone applications, automation in accounting, the internet of things, and future developments in driverless vehicles. The cost–benefit or payback on these types of technology makes it difficult to consider the continuation of human employees in some roles. For example, a supermarket self-checkout system costs \$125,000 (this cost is expected to fall and vary from country to country) for four lanes (Human-Use Experience, 2015). Depending on the country, this is generally lower than or equal to paying four minimum wage employees for an average 40-hr week for a year. Considering the self-checkout system can work 24 hr per day, 7 days a week, and the employer does not have to pay taxes, pensions, health benefits, other benefits, or give breaks to the self-checkout, it is clear which option is

more economically viable for the retailer. The same will be applied to driverless vehicles once the technology is refined.

Interestingly, STARA is not being implemented into just low-paid, low-skilled positions. Sophisticated algorithms are being used in legal research: for example, the Clearwell system was programmed to analyse and sort 570,000 documents in 2 days (Frey & Osborne, 2013), a job that would have normally been conducted by lawyers and paralegals. In addition, report-writing algorithms within business and news media will become more common. Furthermore, the costs of robots with high-precision dexterity are falling significantly (Frey & Osborne, 2013).

A study of 702 occupations detailed the probability of computerisation (i.e., STARA) taking jobs. For example, jobs at risk include accountants, market research analysts, commercial pilots, customer service, sales staff, and office/administration workers, etc. (Frey & Osborne, 2013). STARA could also have a significant effect on medical (Bloss, 2011; Lorentziadis, 2014), education (e.g., with online mass learning), transportation, farming, forestry, and fishing industries. Overall, this seminal research suggested that 47% of jobs are at risk of being taken by STARA (Frey & Osborne, 2013). Many of these jobs are not low-skilled positions, but high-paying middle-class jobs, and many of these jobs are in the service sector. This comes at a time where income inequality is on the rise (Goos & Manning, 2007; Goos, Manning, & Salomons, 2009; David & Dorn, 2013). This is a significant problem given 'household wealth in New Zealand was concentrated in the top 20 percent of New Zealand households, which held about 70 percent of total household net worth' (Statistics New Zealand, 2016: 1). This report shows the widening divide between the 'Haves and the Have Nots' (McCammon, 2016).

If the profession does not fall into the high-risk category it can still be disturbed by STARA within other industries. For example, the need for driving instructors and licence testing officers could be made redundant with driverless cars, as well as insurance assessors, panel beaters, etc. (since driverless cars have the potential to lower crash rates). In addition, it has been proposed that personal motor vehicles will be able to drive through the night while people sleep, putting strain on the accommodation and airline industries (Zaldivar, 2015). *The Economist* (2014) warns that new technologies may take jobs that will not be replaced. Based on these potential workplace changes, the main purpose of this research is to (1) develop a measure that captures STARA awareness; (2) test STARA awareness to determine whether employees perceive it as a threat to their job/career; and (3) determine what effect (if any) STARA has on a range of job and well-being outcomes of current employees. We draw on the career planning literature in relation to STARA perceptions.

LITERATURE REVIEW

Industrial revolutions: history repeating?

Significant changes to the workplace have been seen before, and are considered to be the norm. Broadly speaking, the primary (farming/mining) sector and secondary (manufacturing) sector have shrunk dramatically in many developed nations (Dennis, 1978; Charles, Hurst, & Notowidigdo, 2013). Typically, in these economies, many of the displaced employees transitioned into the tertiary (service) sector over time as new jobs were created (Spohrer & Maglio, 2008). Mechanisation of textiles, steam power, improvements in transportation, production lines, specialisation of labour, electricity, greater communication, and many other factors have driven these revolutions (Jensen, 1993). Electrification within manufacturing was a key driver in 'hollowing out' the skills distribution (Gray, 2013). Gray (2013) suggested that when low-skilled jobs were lost in this way the demand for clerical and management staff jobs was created. However, this might not be the case with our next revolution. The increase of efficiency from technology like STARA creates a situation where middle-class jobs are

disappearing from the market (Feng & Graetz, 2015). The incentive to replace employees within the service sector is the greatest, as the wages of middle-class professions often account for a large amount of the overheads within a given business. What is more concerning is that affected workers within the service sector may not have a 'fourth' industry sector or range of new jobs to transition into immediately. The effect of STARA in the service sector will be like a new industrial revolution and will take decades to play out (Brynjolfsson & McAfee, 2011).

The effect of technology has created skill and wage polarisations within the labour force since the 1950s (Mishel, Schmitt, & Shierholz, 2013). David and Dorn stated that 'polarization stems from the interaction between consumer preferences, which favor variety over specialization, and the falling cost of automating routine, codifiable job tasks' (2013: 1553). The present study works from the assumption that we are on the cusp of a new revolution within the service sector as a result of STARA. It works on the assumption that large numbers of employees could be displaced as a result of STARA relatively soon as per Frey and Osborne (2013). It is not known if more and different jobs will be created as a result, or the middle- and low-skilled workers will be worse off as a result. However, at this point, experts such as Stephen Hawking have pronounced 'warnings' that at the moment robots are taking human jobs and are moving society towards more inequality (Rathi, 2015). Regardless of what the future holds, the present study suggests that there is little empirical research regarding the level of employee awareness of these potential changes. Consequently, there is little known about whether employees are planning new career paths factoring in the potential for STARA. As such, we now discuss career planning and formulate our hypotheses.

Career planning and STARA

STARA awareness captures the extent to which an employee views the likelihood of Smart Technology, Artificial Intelligence, Robotics and Algorithms impacting on their future career prospects. This approach, developed for this study, is positioned within the career-planning literature with Greenhaus and Kopelman (1981), suggesting that career planning has several key and sequential parts. These parts are based on the information surrounding: (1) one's interests, values, and talents, (2) the workplace opportunities, and (3) work-family/leisure interests. The individual may also have their own goals and strategies to achieve their desired career outcomes. Overall, career planning 'refers to individuals' outlining future career developments and to their setting and pursuing career goals' (Zikic & Klehe, 2006: 393). It is important to note that career planning is an ongoing process that is assessed and carried out over one's lifetime. Early career-planning research by Gould (1979) suggested that employees with higher levels of career planning had more effective careers.

The impact from STARA is also likely to increase the prominence of the boundaryless career. Boundaryless careers are seen and defined as 'the opposite of "organizational careers" – careers conceived to unfold in a single employment setting' (Arthur & Rousseau, 2001: 5). They are particularly relevant and prominent when organisations and employees are trying to 'adapt to the modern economic era' (Arthur, 1994: 296), due to cost pressures and disruptive technology. Inkson summarised what is happening to careers by stating that 'the old picture of stable employment and associated organizational careers is fading' (2006: 297). The way we view careers needs to be dynamic, ever changing, and unexpected. However, we could see these changes to careers as opportunities that could be capitalised on (Krumboltz, 2009).

Given that STARA is likely to change employment in a profound way, it is expected that the very nature of career planning is at a pivotal time. For example, if we take the future predictions from Frey and Osborne (2013) and look at them based on the traditional model of career planning (Greenhaus & Kopelman, 1981; i.e., assessing values, talents, workplace opportunities, and work-family/leisure interests), there is a large disconnect. This is important because Baruch discussed the rate of change

with technology, and how these changes 'have wide implications for the management of people at work, and in particular the planning and managing of careers' (2004: 58).

If the predictions of Frey and Osborne (2013) are even partly correct, workplace opportunities could be reduced significantly, making it harder to plan one's career. This in part makes an employee's values and talents, as well as work–family/leisure interests, irrelevant to the career-planning process. For example, an employee with a personal love of vehicles and a talent for driving long periods can still be replaced by driverless vehicles. Within the career-planning process, we consider STARA awareness to be an extension or a part of how an employee considers their future career prospects within their current job, workplace and industry. We now develop our hypotheses.

STARA and job outcomes

The career-planning model put forward by Aryee and Debrah (1993) highlighted the effect that career planning has on other aspects of work. For example, successful career planning leads to a strategy being formed to meet one's goals, which in turn affects career satisfaction. Career satisfaction then promotes self-esteem at work and overall commitment to one's career (Aryee & Debrah, 1993). The following section highlights how STARA could affect a range of job outcomes (i.e., organisational commitment, career satisfaction, and turnover intentions).

Chen, Chang, and Yeh (2004) focussed on the effects of career-development programmes and career needs within research and development firms. Overall, they found that when there was a gap between career-development programmes and career needs, the employees' job attitudes were affected, for example, by having higher turnover intentions. Employees need to feel that their employer is providing them with adequate training, support, and other developmental programmes that enable them to move forward with their careers. Although Chen, Chang, and Yeh (2004) did not measure this empirically, they also suggested that bridging the gap between career-development programmes and career needs could also affect productivity and organisational commitment. Indeed, career planning is linked to important job attitudes (Steffy & Jones, 1988).

We expect STARA awareness to have a similar detrimental influence on the key job outcomes of organisational commitment, career satisfaction, and turnover intentions, as STARA can threaten a person's overall career development and make it more challenging to fulfil one's needs. For example, working for an employer who actively explores and trials robotics to replace employees is likely to be perceived by an employee that they are undervalued and not regarded highly by their employer. This is likely to lead to lower organisational commitment and higher turnover intentions. In effect, it becomes harder for the employee to feel like they are 'part of the family' (Meyer, Allen, & Smith, 1993) if management is exploring ways to replace workers with STARA. It has also been found that commitment to one's career can be negatively related to job withdrawal intentions (Aryee & Tan, 1992). With STARA potentially signalling that an employee's job is in jeopardy, this could encourage the consideration of alternative employment.

Finally, amongst the job attitudes, the present study also focusses on career satisfaction. Aryee and Debrah found that a 'career plan was related to the development and implementation of career strategy which in turn, was related to career satisfaction' (1993: 120). They also suggested that this reinforced the idea that this individual had control over their external environment. We expect that STARA awareness will pose a threat to feelings of control – with the external environment potentially influencing an employee's perceptions of attaining their career goals. This is likely to have a negative influence on career satisfaction. Based on the various findings in the career-planning literature, we suggest STARA awareness will be detrimental to job outcomes and posit the following.

Hypothesis 1: STARA awareness will be negatively associated with organisational commitment.

Hypothesis 2: STARA awareness will be negatively associated with career satisfaction.

Hypothesis 3: STARA awareness will be positively associated with turnover intentions.

STARA and well-being outcomes

We suggest that STARA awareness will not only influence job outcomes, but also well-being outcomes. The way an employee builds their identity with their career and measures their own career success can have an impact on psychological well-being (Mirvis & Hall, 1996; Wiese, Freund, & Baltes, 2002). It is expected that when one's future prospects are lessened, well-being will suffer. For example, job insecurity within the workplace can have a significant effect on employees' mental health. Research from Dekker and Schaufeli (1995) focussed on an organisation during a time of significant organisational change, and they observed that job insecurity was a predictor of psychological health (i.e., psychological stress and burnout). Overall, Dekker and Schaufeli came to the conclusion that long-term uncertainty in a job was more detrimental than knowing whether one was going to be made redundant, stating that the 'silence from above surely erodes the extent to which workers experience control over the future of their jobs' (1995: 62).

It is clear that this uncertainty around the future of work and career could be harmful for some employees. Chen, Chang, and Yeh (2004) suggested that when needs are unsatisfied within one's career options there could be a development of nervousness and stress within a workplace. We expect STARA awareness to contribute to this development of nervousness and stress. However, at the opposite end of the scale, those who are blissfully unaware of the changes that are taking place may cope better than those who know their career prospects could be limited due to STARA. Mirvis and Hall stated that 'One prominent way that working people have coped with disillusionment is by sliding into cynicism ... in doing so they lower their expectations of commitments to an employer' (1996: 377). We thus explore two well-being outcomes: depression and cynicism. Depression has been thought of as 'low pleasure and low arousal' (Axtell et al., 2002: 222), while cynicism relates to 'indifference or distant attitude of work, and having a callous and cynical attitude to work' (Roche & Haar, 2013: 519). We therefore argue that STARA awareness will leave an employee with lower levels of arousal and pleasure (e.g., 'an inanimate object – a robot – may do my job better!') and similarly lead to cynicism and indifference at work (e.g., 'why bother with this job, once the robot is programmed I'll be given the boot'). This leads to the next set of hypotheses.

Hypothesis 4: STARA awareness will be positively associated with depression.

Hypothesis 5: STARA awareness will be positively associated with cynicism.

Moderation effects

The present study also tests the moderation effects of age. Career planning is very important for high school students (Bardick, Bernes, Magnusson, & Witko, 2007), and this process can even begin in early childhood (Magnuson & Starr, 2000). One's age is an important factor to consider when focussing on careers (Morrow & McElroy, 1987). A study of future planning by Prenda and Lachman (2001) found that people planned for the future less as they got older. Thus, the importance of career planning is much more salient for a 25 years old than for a 60 years old. Overall, the career-planning process is ongoing, and it is widely accepted that younger individuals, being at the start of their careers, plan more than older employees, who are at the end of their careers, and will likely stay in their current profession until retirement (Morrow & McElroy, 1987). We suggest that younger employees are more likely to be considering career planning and are more likely to be aware of

potential future disruptions, such as STARA. In addition, it is expected that younger employees are more likely to be researching and considering their career options with more vigour as they enter the workforce.

A meta-analysis with age and career found that 'the relationship between commitment and turnover (actual and intended) is stronger in the early career stage than in the mid and late-career stage' (Cohen, 1991: 253). Furthermore, we suggest that younger employees are more likely to be savvy about technology and, relatedly, have a greater understanding of its potential. Chan-Olmsted, Rim, and Zerba (2013) report that young people are more accepting of mobile technology, while Niehaves and Plattfaut (2014) confirm that technology use is higher amongst younger people. As such, we suggest that younger employees are more likely to be aware of technology and thus the potential for STARA to take their jobs. Hence, we hypothesise that younger employees will have higher STARA awareness than older employees and that age will moderate the influence of STARA awareness on outcomes, with a stronger and more detrimental influence being shown amongst younger employees. This leads to our last hypothesis.

Hypothesis 6: STARA awareness will be significantly higher amongst younger employees than older employees.

Hypothesis 7: Age will moderate the effects of STARA awareness on outcomes, with younger employees having more detrimental effects from STARA than older employees.

METHOD

Research context

The following research took place in New Zealand, which is a highly developed country both socially and economically, and is ranked as the seventh most highly developed country in the Human Development Index (Geohive, 2013). Like many developed Western nations, New Zealand has moved away from employing large numbers of people in agriculture and manufacturing, to employing large numbers of people in the service sector. This is reflected in the country's gross domestic product (GDP), which shows steady declines in the primary and manufacturing industries from the 1970s onwards (Statistics New Zealand, 2012). There has been significant growth in the service sectors (i.e., retail, real estate, finance, insurance, scientific, and technical services) since the 1970s (Statistics New Zealand, 2012). The service sector currently accounts for 71% of GDP (The New Zealand Treasury, 2012).

Procedure

The present study used research assistants to distribute surveys. These research assistants used a combination of online and paper-based surveys (both surveys were identical) to collect the data. Purposeful sampling was undertaken to attract a broad range of employees within the service sector (Coyné, 1997). The service sector was targeted in this study because of its prominence within New Zealand, as within many other Western nations. Furthermore, it is expected that the effects of STARA will be felt greatest within the service sector. This is because the primary and secondary sectors have already seen the effects of automation, as well as the exportation of jobs offshore to countries with low-cost labour.

Over 200 organisations within New Zealand were approached, including private businesses. The purpose of the study and its requirements were explained to participants by the research assistants and a survey cover letter. Exact numbers of the number of surveys distributed were recorded by the research assistants. In total, 420 online and physical surveys were distributed, and 120 participants responded to

the survey, the response rate for this study was 28.6%. Research on the differences between paper-based and online surveys showed there to be little difference between the overall mean scores and variance within the data (Deutskens, de Ruyter, & Wetzels, 2006). Ethics approval was granted by the first author's University ethics office (Massey University).

Sample

On average, participants were 32.0 year old ($SD = 12.3$ years), married or in a relationship (54.2%), female (69.2%), and had job tenure of 4.9 years ($SD = 5.8$ years). On average, respondents worked 34.9 hr per week ($SD = 12.0$ hr/week). Overall, education was well spread: 37.5% had a high school qualification, 20.8% had a technical college qualification, 26.7% had a university degree, and 7.5% had a postgraduate qualification. Due to a significant decline in union membership in New Zealand (Ryall & Blumenfeld, 2014), the majority of employees are working on individual rather than collective agreements. In our study, 89.2% of respondents were on individual employment agreements.

Like the majority of employees studied, all questions were asked in the same survey at the same time, thus creating potential for common-method variance. One test of common-method variance (Podsakoff, MacKenzie, Lee, & Podsakoff, 2003) is Harman's One Factor Test and the factor analysis (unrotated) resulted in seven factors, with the largest factor accounting for less than 30% of the overall variance. This suggests that common-method variance is not an issue (Podsakoff & Organ, 1986).

Measures

Organisational Commitment was measured with a 6-item scale (Meyer, Allen, & Smith, 1993), coded 1 = 'strongly disagree,' to 5 = 'strongly agree'. A sample item from this measure is 'I do not feel "emotionally attached" to this organisation'. The present study found this measure to be robust ($\alpha = 0.75$). Career Satisfaction was measured using a 5-item scale (Greenhaus, Parasuraman, & Wormley, 1990), coded 1 = 'strongly disagree,' to 5 = 'strongly agree'. The sample question was 'I am satisfied with the success I have achieved in my career' and 'I am satisfied with the progress I have made toward meeting my overall career goals'. The present study found this measure to be robust ($\alpha = 0.89$). This is consistent with another study that used that measure within New Zealand (Haar & Brougham, 2013). Turnover Intentions were measured with a 4-item scale (Kelloway, Gottlieb, & Barham, 1999), coded 1 = 'strongly disagree,' to 5 = 'strongly agree'. Sample items from this measure are 'I am thinking about leaving my organisation' and 'I intend to ask people about new job opportunities'. The present study found this measure to have excellent reliability ($\alpha = 0.94$).

Depression was measured with three items from the Axtell et al. (2002) scale. The question stem was presented: 'Thinking of the past few weeks, how much of the time has your own job made you feel each of the following?' and was followed by three adjectives: 'Depressed', 'Gloomy', and 'Miserable'. The present study found this measure to be very robust ($\alpha = 0.95$). This is consistent with another study that used the short measure within New Zealand (Brougham & Haar, 2013), and the full measure has been validated internationally (Spell & Arnold, 2007a, 2007b). Cynicism was measured with a 5-item scale (Maslach & Jackson, 1981). A sample item is 'I have become less interested in my work since I started this job' and 'I have become more cynical about whether my work contributes anything'. The present study found this measure to be robust ($\alpha = 0.86$).

STARA Awareness was measured using four items developed for this study, based on the job insecurity measure by Armstrong-Stassen (2001). We initially defined STARA for respondents stating 'Smart Technology, Automation, Robotics and Artificial Intelligence (STARA) are expected to change

TABLE 1. RESULTS OF EXPLORATORY FACTOR ANALYSIS FOR SMART TECHNOLOGY, ARTIFICIAL INTELLIGENCE, ROBOTICS, AND ALGORITHMS (STARA) AWARENESS

<i>Questions followed the stem 'Thinking of your current job, please answer the following' and responses were coded 1 = 'strongly disagree', to 5 = 'strongly agree'</i>	ITC	FL
1. I think my job could be replaced by STARA	0.536	0.700
2. I am personally worried that what I do now in my job will be able to be replaced by STARA	0.756	0.876
3. I am personally worried about my future in my organisation due to STARA replacing employees	0.815	0.922
4. I am personally worried about my future in my industry due to STARA replacing employees	0.727	0.875
Eigenvalues		2.874
Percentage variance		71.9%
Number of items in measures		4 items
Cronbach's α		0.85

Note. FL = factor loadings; ITC = corrected item-total correlations (item scores correlated with the sum of all other item scores).

some workplaces and jobs within the next 10 years'. This was then followed by the question stem: 'Thinking of your current job, please answer the following'. The items asked and analyses are shown in Table 1.

To confirm the factor structure, we conducted factor analysis (principal components, varimax rotation) and the 4 items loaded onto a single factor with eigenvalues >1 (2.874) accounted for a sizeable amount of variance (71.9%) and achieved very good reliability ($\alpha = 0.85$).

Corrected item-total correlations were all >0.50 , with a mean corrected item-total correlation of 0.62, and all factor loadings of all items were >0.50 , ranging from 0.700 to 0.922. As these results are similar to the analysis by Allen regarding a new measure created, we argue that 'the results provided support for the reliability of the measure and indicated that the items were measuring a single global construct' (2001: 423).

The moderator Age was measured in years. Control variables included a range of typical demographic variables: gender (1 = female, 0 = male), education (1 = high school, 2 = technical qualification, 3 = university degree, 4 = postgraduate qualification), ethnicity (1 = white, 0 = nonwhite), organisational tenure (years), and hours worked (per week). Finally, Job Insecurity was measured with a 3-item scale by Armstrong-Stassen (2001), coded 1 = 'strongly disagree,' to 5 = 'strongly agree'. A sample item from this measure is 'Are you personally worried about your job security?'. The present study found this measure to be robust ($\alpha = 0.82$). We control for job insecurity because traditional psychological contract theory is one where employees are provided with job security in return for hard work and performance (Virtanen, Kivimäki, Virtanen, Elovainio, & Vahtera, 2003). However, we expect those employees with a greater understanding of STARA to feel less secure about their jobs, as they can see the potential for their job being codified and automated. In this regard, there is no security for working hard. A designer or programmer may create a robot/algorithm to do what an employee does and then their job is simply replaced.

Analysis

We used hierarchical multiple-regression analysis (Cohen & Cohen, 1983) to test the influence of STARA awareness on job and well-being outcomes. In total, five models were run, with control variables (gender, education, organisational tenure, hours worked, and job insecurity) entered in Step 1. Step 2 held the STARA awareness construct and Step 3 age (as the moderator). Step 4 held the

interaction between STARA awareness and age. The centring procedure (Aiken & West, 1991) was followed where all interacting variables were *z*-scored.

Open-ended question

The present study also used an open-ended question to capture participants' comments regarding STARA awareness, how it affects their current job and also how it might impact on their future career prospects. Mixed-method research is growing in popularity, and enables the best aspects of both quantitative and qualitative research (Creswell & Plano Clark, 2007; Östlund, Kidd, Wengström, & Rowa-Dewar, 2011). Of the 120 participants, 67 participated in this open-ended question (53 left it blank). A thematic analysis (i.e., both authors independently and then together coded responses) generated three broad thematic categories: (1) No threat (participants do not envisage STARA affecting their current job or career), (2) Potential threat (participants can envisage STARA playing a role in their future job or career), and (3) The threat is real (participants are aware of STARA being used within their current job and/or being deployed in the very near future).

RESULTS

Descriptive statistics for all the study variables are shown in Table 2.

Table 2 shows that STARA awareness is low, with a mean score of 1.7 (SD = 0.77) and a mid-point of 3. As such, the overall perception of technology replacing employees' jobs appears low. That said, as expected STARA awareness is significantly correlated with outcomes in the expected direction: organisational commitment ($r = -0.29, p < .01$), career satisfaction ($r = -0.32, p < .01$), turnover intentions ($r = 0.29, p < .01$), depression ($r = 0.25, p < .01$), and cynicism ($r = 0.33, p < .01$). STARA awareness is also significantly correlated with age ($r = -0.29, p < .01$).

We confirmed this by recoding age into three categories (1, ≤ 30 years; 2, 31–50 years; and 3, ≥ 51 years) and conducting an analysis of variance test in order to compare the age groups for significant differences (Haar, Russo, Suñe, & Ollier-Malaterre, 2014), using the recommended *post hoc* analysis tests of Fisher least significant difference and Student–Newman–Keuls. We found significant

R ² change	0.04*	0.03 [†]	0.04*	0.01	0.00
Total R ²	0.31	0.32	0.21	0.19	0.23
Adjusted R ²	0.24	0.25	0.13	0.10	0.15
F statistic	4.258***	4.511***	2.529*	2.228*	2.893**

Note. Standardized regression coefficients, all significance tests were two-tailed.

STARA = Smart Technology, Artificial Intelligence, Robotics, and Algorithms.

[†] $p < .1$, * $p < .05$, ** $p < .01$, *** $p < .001$.

differences across the age groups ($F = 6.022$, $p < .01$), with *ad hoc* analysis showing the youngest group (30 years and under) had significantly higher STARA awareness ($M = 1.9$) compared with both other groups (both $p < .05$); the oldest group (over 50 years) with $M = 1.2$, and the middle group (31–50 years) at $M = 1.6$. Overall, this provides support for Hypothesis 6 that younger respondents would have higher STARA awareness.

The results of the moderated regression analysis for the study hypotheses are shown in Table 3.

Direct effects

Table 3 shows that the outcomes and Hypotheses 1–5 were all supported, with STARA awareness being significantly related to organisational commitment ($\beta = -0.21$, $p < .05$), career satisfaction ($\beta = -0.37$, $p < .001$), turnover intentions ($\beta = 0.30$, $p < .01$), depression ($\beta = 0.25$, $p < .05$), and cynicism ($\beta = 0.34$, $p < .001$). From Step 2 we can see that STARA awareness accounts for a small amount of variance regarding organisational commitment (4%, $p < .05$), more modest amounts regarding depression (6%, $p < .05$) and turnover intentions (9%, $p < .01$), and a larger amount still for cynicism (12%, $p < .001$) and career satisfaction (13%, $p < .001$). Amongst the control variables, hours worked is consistently beneficial towards all job outcomes: organisational commitment ($\beta = 0.29$, $p < .01$), career satisfaction ($\beta = 0.31$, $p < .01$), and turnover intentions ($\beta = -.23$, $p < .05$). The other significant control variable is job insecurity, which was significantly related to career satisfaction ($\beta = -0.25$, $p < .05$), depression ($\beta = 0.19$, $p < .1$), and cynicism ($\beta = 0.21$, $p < .05$). Overall, the

control variables block accounted for sizeable variance, ranging from 9% (nonsignificant) to 21% ($p < .01$) across all models.

Moderation effects

We tested age as a moderator of STARA awareness and three significant interactions were found on the job outcomes (there was no significant interaction on well-being outcomes). The significant interaction effects were on organisational commitment ($\beta = 0.25$, $p < .05$), career satisfaction ($\beta = 0.20$, $p < .1$), and turnover intentions ($\beta = -0.26$, $p < .05$). The interaction Step accounted for an additional 4% ($p < .05$) to organisational commitment, 3% ($p < .1$) to career satisfaction, and 4% ($p < .05$) to turnover intentions. Graphs of the interactions are presented in Figures 1 and 2. Because the graphed effects for organisational commitment and career satisfaction are very similar, we graph these together (in Figure 1).

Figure 1 shows that at low levels of STARA awareness there is little difference in terms of organisational commitment and career satisfaction with respect to age. However, at high levels of STARA awareness, significant differences are found. Older employees hold fairly stable levels of organisational commitment and career satisfaction, while younger respondents report a significant drop in organisational commitment and career satisfaction.

Figure 2 shows that at low levels of STARA awareness there is a significant difference in terms of turnover intentions, with younger respondents reporting much higher turnover intentions. At high levels of STARA awareness, these significant differences are exacerbated, with older employees holding fairly stable levels of turnover intentions, while younger respondents report a significant increase in turnover intentions. Combined, these findings support the hypothesis that the influence of STARA awareness would be moderated by age, with younger employees being more adversely affected.

In summary, STARA awareness was negatively associated with organisational commitment and career satisfaction supporting hypothesis one and two. STARA awareness was also positively associated with turnover intentions, depression, and cynicism supporting Hypotheses 3–5. The present study also found that younger employees had more STARA awareness which in turn moderated the effects of STARA awareness on outcomes supporting Hypotheses 6 and 7.

FIGURE 1. INTERACTION OF AGE ON SMART TECHNOLOGY, ARTIFICIAL INTELLIGENCE, ROBOTICS, AND ALGORITHMS (STARA) AWARENESS WITH ORGANISATIONAL COMMITMENT AND CAREER SATISFACTION AS DEPENDENT VARIABLES

FIGURE 2. INTERACTION OF AGE ON SMART TECHNOLOGY, ARTIFICIAL INTELLIGENCE, ROBOTICS, AND ALGORITHMS (STARA) AWARENESS WITH TURNOVER INTENTIONS AS DEPENDENT VARIABLE

Qualitative results

The three thematic codes are split into sections within Table 4. The table displays 32 quotes out of a potential 67 participants who responded to this question.

Results from Table 4 highlight people's perception of STARA from a wide range of professions. In total, 35 quotes were coded as 1 (no threat from STARA), 18 quotes were coded as 2 (potential threat from STARA), and 14 quotes were coded as 3 (perceived a real threat from STARA). Overall, there is a wide spread of comments amongst the responses and this reflects the quantitative data of STARA awareness somewhat (with a low $M = 1.7$, on a 1–5-point scale). Examples of those registering *no threat* are all coded 1, with a specific example being 'Because human interaction is a lot different compared to a robot and it isn't the same and bar work and making drinks is a fine art if you do it the right way' (No. 2, bartender). Examples of those seeing a *potential threat* are coded 2, and a specific example is 'It could certainly help with aspects of the job but there is also a lot of human based aspects that would still be required, it could be a threat but I think there is still a need for human interaction' (No. 26, travel agent). Finally, a specific example of a *real threat* is 'Smart technology will assist in making transport solutions more appealing to the customer ... Driving buses/taxis is already happening so operationally there is room for this' (No. 29, manager transport services). We make additional references to the comments in the discussion.

DISCUSSION

The present study sought to explore employee STARA awareness and whether they consider new technology taking their job or changing their career. With a mean score of 1.7 (on a 1–5 scale), it would appear there is little belief in the idea of robots and automation taking over jobs in the workplace. This is also reflected in the results from the qualitative quotes (and subsequent coding of these quotes), which provide an insight into the proportion of participants who were aware of STARA in their current job or career. Whether the quantitative or qualitative responses represent 'ignorance is bliss' or 'keen insight' is currently unknown, and we must remember that the potential for STARA is simply that: *potential*. No one knows for certain how much the workplace and workforce will change

TABLE 4. QUALITATIVE THEMATIC ANALYSIS ON SMART TECHNOLOGY, ARTIFICIAL INTELLIGENCE, ROBOTICS, AND ALGORITHMS (STARA) AWARENESS

<i>ID No.</i>	<i>Job title</i>	<i>Outlook on changes to future job and career prospects</i>
Coded: No threat		
1	Bartender	My personal situation will not change at all in the industry I'm in to a great extent. Certain ways could be enhanced for sure but it can't be run on artificial intelligence
2	Bartender	Because human interaction is a lot different compared to a robot and it isn't the same and bar work and making drinks is a fine art if you do it the right way
3	Business analyst	Not sure that it will. Personally think that it's not going to make a material difference in my line of work in my lifetime
4	Business support	We work in the service industry, robots are irrelevant
5	Physical activity educator	I don't believe STARA could replace my role in the workplace
6	Physical activity educator	I don't see STARA having an effect as my role is all about the interpretation of each client's unique health status. This interpretation requires personal interaction with the patient that technology, at this point, capable of
7	Senior service desk team leader	I don't think it will, not in this role, it still requires human intervention to ensure that things are being delivered
8	Storeroom assistant	It won't affect my career at all
9	Manager	I don't see it impacting
10	Manager	Not very much at all
Coded: Potential threat		
11	Bartender	I guess they could use a robot to do it but it'd be a bit weird and hospitality is based on interacting with customers so I fail to see how a robot could bring personality to the position
12	Customer service	My current job would be done on screens instead of face to face interaction
13	Customer service	It might be hard for me to find a job
14	Executive	Some written interactions could be generated as part of an automated process if we had the right technology
15	HR manager	STARA will mean that the process part of HR will be more automated (e.g. recruitment, on boarding etc.). However, much of HR will still need people rather than STARA. However, I will need to get more IT savvy to stay current in my role in the future
16	HR manager	Automated standardised processes. Change the focus of HR – we are people based therefore the focus of HR will move away from transactional/functional HR
17	HR manger	STARA will be able to carry out routine tasks particularly related to recruitment and selection processes and other repetitive system activities which would then free people up to carry out the more complex 1:1 and group activities with complex dynamics with soft skills
18	Manager	There are opportunities for automation of some aspects of the work undertaken by my staff and I need to remain familiar with technological development which may enable efficiency gains through automation
19	Retail manager	Fewer job opportunities due to automated replacements. It will also require the skill level of employees to be higher to warrant hiring
20	Service delivery manager	Because my role requires many managerial skill-sets, along with human intuition and interaction, I don't believe STARA will have much of an impact on my future career prospects. However with smart technology and automation, future jobs and tasks I have to perform within a role may become more efficient
21	Service delivery manager	STARA will more than likely replace the repetitive tasks within my role. AI could potentially replace data analysis (data mining) that I currently do, to find trends, risks and causes of issues
22	Service delivery manager	Because my role requires many managerial skill-sets, along with human intuition and interaction, I don't believe STARA will have much of an impact on my future career prospects. However with smart technology and automation, future jobs and tasks I have to perform within a role may become more efficient
23	Service technician	Smart tech could be used in reports, record keeping and remote availability of records
24	Service technician	It will have a large influence on controlling appliances and plants that we work on I think and we will have to move to get a better understanding of it but I like to think we will still be required, our understanding and knowledge of STARA will have to keep up with advances for us to be useful though
25	Storeroom assistant	Would possibly eliminate positions requiring manual handling positions and therefore eliminate the need for a career in the distribution industry
26	Travel agent	It could certainly help with aspects of the job but there is also a lot of human based aspects that would still be required, it could be a threat but I think there is still a need for human interaction
27	Manager	Smart technology can certainly help to provide the data/analysis from which to work from. However the role that I am in requires a lot of human interaction which I believe at this time cannot be replaced by STARA

TABLE 4. (Continued)

ID No.	Job title	Outlook on changes to future job and career prospects
		Coded: Real threat
28	Customer service	People being able to put serve themselves on Point of Sale, enrol themselves in classes etc. will eventuate. Leaving a customer service department with less work = less hours for some people
29	Manager transport services	Smart technology will assist in making transport solutions more appealing to the customer. I can't see AI getting too involved in our sector from a management point of view. Driving buses/taxis is already happening so operationally there is room for this. However at a strategic level I can't see it yet
30	Nurse	Not sure that it would – as I am not in clinical contact with patients within the health system, however I believe some tasks of hands on nursing have already been trialled with STARA technology
31	Business analyst	STARA will more than likely replace the repetitive tasks within my role. AI could potentially replace data analysis (data mining) that I currently do, to find trends, risks and causes of issues
32	Customer service	They will replace staff with self-checkouts

and what role technology will play. However, the findings from the present study offer an interesting insight into how individuals view their future employment and career prospects, and how those views affect their job and well-being outcomes. Employees should consider their career opportunities and how they relate to STARA.

The results from the study show that when employees are more aware of STARA and its application to their job, they are more likely to have lower organisational commitment and career satisfaction. This falls into line with the career-planning model put forward by Aryee and Debrah (1993), who suggested that career planning can promote a positive cycle that increases career satisfaction and self-esteem at work. Consequently, the advent of STARA might spell the end to successful career planning and thus lead to the detrimental effects found here, reinforcing turbulent changes of a boundaryless career, which could become more prevalent in the future due to technology changes. In addition, employees with a higher perception of STARA are likely to have higher adverse effects on turnover intentions, depression, and cynicism. Overall, the findings from the study are not surprising considering that 'unmet growth-related career expectations, in turn, have been associated with stress, burnout, and turnover intentions' (Virtanen et al., 2003: 31).

Interestingly, STARA was found to not be significantly correlated to job insecurity, and this suggests it may indeed be tapping into something at the core of fundamental work and career planning. With job insecurity, an employee may face losing their job and have to look for another one. With STARA, the job and entire industry of employment might disappear. Indeed, some qualitative comments reflected strong STARA awareness but no loss of jobs. For example, No. 29 stated 'I can't see AI getting too involved in our sector from a management point of view ... at a strategic level I can't see it yet'. This reflects strong STARA awareness but not a personal loss of job, possibly highlighting the lack of STARA awareness and job insecurity correlating significantly.

It is clear that employee loyalty and commitment have been reduced as the prospect of lifetime employment in one organisation has slipped away (Mirvis & Hall, 1996): this is especially true with the rise of temporary contracts. STARA could be seen as part of this progression of undermining long-term commitment within an organisation or industry. Baruch discussed the importance of employees moving away from commitment and loyalty, stating that 'From the individual perspective, it is a farewell to traditional commitment to the organization, moving to multiple commitments, which include merely a conditional commitment to the organization' (2004: 59). This outlook on commitment, and indeed commitment to one's career, might have to be the future expectation for many employees. However, employees may already view traditional careers as something of the past, and be

far more open to the idea of boundaryless careers that are dynamic and ever changing based on the employment context.

In addition to the contribution of linking STARA with job and well-being outcomes, there was consistent support for interaction effects on the job outcomes. Overall, at high levels of STARA awareness, older employees have little difference in commitment, career satisfaction, and turnover intentions compared with those respondents with low STARA awareness. This could be because older employees (even those who are aware of the potential of STARA) do not see STARA as a significant threat to their current job and career prospects. For example, Participants 9 and 10, both aged 60–70, stated, respectively, 'I don't see it impacting' and 'Not very much at all'. While this might reflect being blissfully unaware of these potential changes, it is more likely to represent the end of the career cycle for these employees. Hence, for older employees they have less stress and strain from their STARA awareness.

Implications

The present study has a number of implications, especially for individual employees. Current employees should research the impact and likelihood of STARA changing the line of work they are employed in, or are looking to enter. As a result, they might also need to be more mindful about the implications of STARA within their industry, and plan accordingly to accommodate these potential changes. Perhaps employees will also need to move their thoughts away from linear career systems to thinking of careers as multidirectional (Baruch, 2004). Given the rising cost of education, individuals need to commit to areas that are likely to provide them with employment (if employment is the desired outcome from study). As the supply of highly skilled graduates continues, with limited job prospects at the end of many of these degrees (Beaudry, Green, & Sand, 2013), this may create serious challenges for future job seekers. In addition, universities and training institutes need to be aware of industries that are potentially in decline and be careful to not market them as fruitful areas of employment. Bloom (2014) argues that we are at a point where we need to focus on employment rather than employability at a national level.

Finally, one caveat must be noted within all of this: we do not know whether STARA will destroy or create jobs, as job creation has been the result of past industrial revolutions. STARA could potentially create more jobs than it displaces, and take the menial jobs away from the market. It might also reinvigorate the manufacturing base within many Western countries, as labour costs would be removed from the equation. For example, the advent of three-dimensional printing might make it economically feasible to produce products onshore, providing jobs for people within the country, rather than importing these goods from abroad. This new era of change could be considered a time of excitement for some employees; it could be embraced as an opportunity for exploration and personal growth. Ultimately, the future is very difficult to predict, it is interactive, emergent, and dynamic (Pryor, Amundson, & Bright, 2008).

Limitations and future research

The present study has several limitations. Future research should look to develop the sample size and also include employees from both the primary and secondary sectors. This type of research would also benefit from a longitudinal design to track individuals' understanding of technological advancements as time progresses. Furthermore, do certain media landscapes create increased awareness of STARA? For example, if the US President makes an address on the risks to the US future workforce, or driverless cars are made mainstream, employees might consider the wider implications with more seriousness. The present study also makes the assumption (based on Frey & Osborne, 2013) that STARA could

take away jobs. However, it is probable that more and different jobs will be created as a result. Finally, future research might include more specific questions around career planning as well as the potential for career/profession changes that employees might be considering, rather than relying on turnover intentions to capture this. Overall, we encourage more research to provide us with greater clarity and knowledge.

Conclusion

The period we are currently in has been described as a new industrial revolution. As a result we are expecting significant changes to the way we work, and what work will still be available to human employees in the very near future. This research explored how employees view their future jobs and careers in this ever changing world. Overall, the present study highlights the current state of how STARA is perceived regarding job and well-being outcomes. Future studies should be continued in this area to enable employees, employers, and government/policy makers to prepare for these potential changes. It is important that we prepare adequately, as the overall findings show that employees in general do not perceive STARA to be a threat, despite what well respected business people, scientists, and academics are predicting.
