has to be invoked before being proved, but this is unavoidable. It is simply unfair to bomb students taking a first course in differential equations with the Picard theorem at the outset.

Commendable features include: many physical examples (but fewer towards the end); good treatment of numerical methods, including Runge-Kutta; numerous problems (some with answers). Reviewer's complaints: loquaciousness; disorganization; completely inadequate bibliography (why not list all standard useful references in the subject?).

There is no treatment of non-linear equations. Do these by definition belong only in the second course?

Colin Clark, University of British Columbia

Discovering modern algebra, by K. L. Gardner. Oxford University Press, London, 1966. 260 pages.

This is a pleasing, and successful, attempt to introduce, and motivate, the idea of a group, using examples in arithmetic, transformations in geometry, and matrices. There is also a chapter on linear programming. It is suitable for youngsters, in high school say, who already have some inclination towards mathematics. Of course the drawback is that the contents of this 260 page book could be contained in 50 pages and learned in a few hours by students at the second or third year undergraduate level.

William Moser, McGill University

Problèmes de calcul des probabilités, D. Dacunha-Castelle,
D. Revuz et M. Schreiber. Preface du Professeur A. Tortrat. Masson et Cie, Paris, 1965. vi +196 pages. 36 F .

This collection of problems and solutions was compiled for use in the certificate programme in France in the calculus of probability. It includes 15 on combinatorics, 7 on measure theory, 9 on generating functions, 8 on characteristic functions, 6 on convolutions, 7 on conditional probabilities, 9 on normal laws, 6 on Poisson processes, 8 on convergence in law, 6 on the law of large numbers and 5 miscelianeous problems. Within each section they are arrangedin order of increasing difficulty and range from straightforward computation to problems which would challenge most good honors students. This collection of problems fits closely to the text book "Calcul des Probabilités" of A. Tortrat (Masson et Cie., Paris, 1963). In a Canadian university this collection would be a useful supplement to a basic course in probability theory.
D. Dawson, McGill University
