Adolescence and addiction are two different entities. Adolescence is a period characterized by a realignment risk of psychic structures, physiological and morphological. It is constructed using a reference model via the values inherited from the parents and new behaviors including consumption of drug abuse "addiction".

We illustrate our presentation with a literature review done on the PubMed database using keywords such as "adolescent, addiction, neurobiologic,pathogenesis, treatment" to study all the parameters that explain the link between adolescence and addiction from a causal model neurobiology and pathophysiology to develop in a particularities of the therapeutic management of drug abuse among adolescents.
